Requirement Analysis Phase

Project: Implement Client Script & UI Policy (Incident Optimization)

1. System Objective & Functional Scope

The primary objective during this requirement analysis phase is to translate ServiceNow business expectations into enforceable, client-side technical behaviors on the Incident form. The scope encompasses real-time structural data validation to ensure Incident records possess consistent, mandatory, and error-free properties before platform record serialization occurs.

2. Detailed Functional Requirements Matrix

Requirement ID	Trigger / Form Context	Functional Constraint & Rule Target	System Action & Output
FR-01	Form view when Impact field value changes.	Evaluate condition: Is Impact == '1 - High'?	Dynamically set Assignment group to mandatory. Automatically revert rule states if the condition evaluates to false.
FR-02	Form view when Impact field value changes.	Evaluate condition: Is Impact == '1 - High'?	Enforce Urgency field as **Read-Only** via client-side UI configurations.
FR-03	Asynchronous onChange form interaction.	Triggers explicitly when the form Impact value switches to '1'.	Automatically write value '1' into the Urgency field. Broadcast system notice message to user screen interface.
FR-04	Form submission interception (onSubmit).	Evaluate active conditions: Is Impact == '1' and Assigned To is null or empty?	Halt record commit pipeline sequence. Render an explicit error banner beneath the Assigned To field component.
FR-05	Row-based data grid modifications (onCellEdit).	Triggers when an inline cell amendment attempts to alter the State property.	Block transaction execution. Force abort parameters via callback logic and alert the user to apply updates via form view.

3. Non-Functional Requirements & Performance Targets

• **NF-01 (Performance):** Processing logic must be executed inside the local client session context (browser runtime ecosystem) to preserve instance scaling and cut heavy database trips.

• **NF-02 (Reliability):** UI automation mechanics must handle input state rollbacks dynamically (via Reverse if false logic models) to avoid breaking form rules during runtime reassessments.

• **NF-03 (Usability):** Form exceptions and input blocks must be coupled with field markers or clear prompt modal dialogs to guide users to clean records directly.
